AB  The present invention provides a recombinant virus comprising a chimeric
    gene which encodes an intact anti-tumor antibody contg. human Ig const.
    regions and the therapeutic use thereof. By inserting into the genome of
    a recombinant virus a nucleotides acid sequence which simultaneously
    comprises. The cDNA sequences of both light chain and heavy chain gene of
    an intact anti-tumor antibody with human Ig const. regions are inserted
    into the genome of a recombinant virus, and the intact anti-tumor antibody
    can be expressed in tumor cells with high efficiency, thereby inhibit the
    growth and metastasis of tumors. In particular embodiments, the cDNA
    expressing human anti-EGFR antibody, or humanized antibody specific to
    human Her2, and chimeric human-mouse anti-CD20 antibody are prepd. and
    inserted into a replication deficient adenovirus. The anti-tumor activity
    of chimeric human-mouse anti-CD20 antibody is tested in breast cancer cell
    line BT-474 and a nude mouse implemented with breast cancer cell line
    SK-OV-3.

AB The invention refers to an immunogenic recombinant antibody designed for immunization of primates comprising at least a part of a murine IgG2a subtype amino acid sequence and a mammalian glycosylation. The antibody is a chimeric, humanized, monoclonal, anti-idiotypic, or bi-isotopic antibody or fragment. The antigen is an epitope or mimotope of tumor-assocd. antigen, epithelial cell adhesion mol., Lewis Y antigen, NCAM, CEA, T cell epitope, carbohydrate, sialyl-Tn, Globo-H, glycolipid, GD2, GD3 or GM2.

AB The present invention relates to nucleic acid mols., including fusion constructs, having catalytic activity and the use of same in glycosylation engineering of host cells to generate polypeptides with improved therapeutic properties, including antibodies with increased Fc receptor binding and increased effector function. The engineered proteins or antibodies comprise Golgi localization domain of Golgi resident polypeptide such as .beta.(1,4)-N-acetylglucosaminyltransferase III, .beta.(1,4)-galactosyltransferase, mannosidase II, .beta.(1,2)-N-acetylglucosaminyltransferase I, .beta.(1,2)-N-acetylglucosaminyltransferase II, mannosidase I, .alpha.-mannosidase II, and .alpha.1-6 core fucosyltransferase. The effector function includes Fc-mediated cellular cytotoxicity of NK cells, macrophage, polymorphonuclear cells and monocytes; signaling of apoptosis induction; maturation of dendritic cells; or T cell priming. The engineered antibodies include antibodies or humanized antibodies specific to human neuroblastoma, renal cell carcinoma, colon carcinoma, breast carcinoma, lung carcinoma, ***17*** - ***1A*** antigen, CD20, CD22, CD30, CD40, PSMA, EGFR, PSCA, HLA-DR, MUC1, EpCAM, etc.

AB The invention provides methods for producing mixts. of antibodies from a single host cell clone. Thereto a nucleic acid sequence encoding a light chain, and nucleic acid sequences encoding different heavy chains are expressed in a recombinant host cell. The antibodies in the mixts. according to the invention suitably comprise identical light chains paired to different heavy chains capable of pairing to the light chain, thereby forming functional antigen binding domains. Antibodies exemplified in the invention include VL and VH of clones K53 (against CD46), UBS-54 (against ***EP*** - ***CAM*** ), 02-237 (against CD46), B28 (against CD22), II-2 (against CD72) and I-2 (against HLA-DR class II). Such mixts. can be used in a variety of fields.

AB EGP-2, also known as ***Ep*** - ***CAM*** , is expressed at high levels on the surface of most carcinomas and is therefore considered an attractive target for anticancer strategies. To explore the mechanisms regulating the expression of EGP-2, sequences 3.4 kb upstream of the transcription start site were isolated and assayed for their ability to control the expression of the EGP-2 cDNA, the green fluorescent protein, the luciferase reporter gene and the thymidine kinase and cytosine deaminase suicide genes. Expression of these chimeric constructs as assessed in a range of different cell lines was restricted to cell lines expressing EGP-2. In addition, only cells expressing EGP-2 were sensitive for gancyclovir after being transiently transfected with EGP-2 ***promoter*** -driven thymidine kinase. Deletion analyses defined 687 bp upstream as the basic proximal ***promoter*** region, which could confer epithelial-specific expression to the GFP reporter gene in vitro. As these EGP-2 sequences can confer ***promoter*** activity to reporter and suicide genes in an EGP-2 restricted manner, they may be useful for gene therapy of EGP-2 expressing carcinomas.

AB The present invention provides vectors for expressing genomic streptavidin fusion cassettes. In the various embodiments, fusion proteins produced from these vectors are provided. In particular embodiments, fusion proteins comprising a single-chain antibody and genomic streptavidin are provided as are vectors encoding the same. The single-chain antibodies are directed to cell surface antigens, or cell-assocd. stromal or matrix antigens, including, but not limited to, CD20, CD22, CD25, CD45, CD52, CD56, CD57, EGP40 (or EPCAM or KSA), N-CAM, CEA, TAG-72, .gamma.-glutamyl transferase, mucins (MUC1 through MUC7), human .beta.-chorionic gonadotropin, EGF receptor, interleukin-2 receptor, her2/neu, Lewis Y, gangliosides GD2 and GM2, tenascin, sialylated tenascin, somatostatin, activated tumor stromal antigen, or neoangiogenic antigens. Generically, a single-chain Fv/streptavidin (scFvSA) fusion protein is expressed from the genetic fusion of the single-chain antibody of the variable regions to the genomic streptavidin of Streptomyces avidinii. The scFv gene consists of the variable regions of the light and heavy chains sepd. by a DNA linker sequence. The streptavidin coding sequence is joined to the 3'-terminus of the scFv gene, and the two genes are sepd. in-frame by a second DNA linker sequence. The signal sequence from the streptavidin gene is fused at the 5'-terminus of the scFvSA gene to direct expression to the Escherichia coli periplasmic space. The scFvSA gene is under control of the lac ***promoter*** , and the expressed fusion protein is extd. and purified from E. coli and forms a sol. tetramer of .apprx.173,000 mol. wt. Also provided, are methods of using the fusion proteins of the present invention, in the absence and presence of a radiation-sensitizing agent (e.g., Gemcitabine), and in particular, the use of scFvSA fusion proteins as diagnostic markers or as cell-specific targeting agents.

AB A highly sensitive assay is disclosed which utilizes a method for gene specific primed amplification of mRNA libraries from rare cells and rare transcripts found in blood. The assay allows detection of rare, mRNA (10 copies/cell) found in 1 to 10 cells isolated through immunomagnetic enrichment. The assay is an improvement over multiplex PCR and allows efficient detection of rare coding sequences for circulating carcinoma cells in the blood. The methods are useful in profiling of cells isolated from tissues or body fluids and serves as an adjunct to clin. diagnosis of diverse carcinomas including early stage detection and classification of circulating tumor cells. Monitoring of nucleic acid and protein profiles of cells either in conventional or microarray formats, facilitates management of therapeutic intervention including staging, monitoring response to therapy, confirmation of remission and detection of regression.

AB The present invention provides vectors for expressing Streptomyces avidinii genomic streptavidin (SA) fusion cassettes. A genomic streptavidin expressed gene fusion is expressed as a sol. protein into the periplasmic space of bacteria and undergoes spontaneous folding. Such expression offers the advantage that the periplasm is a low biotin environment and one need not purify and refold the protein under harsh denaturing conditions that may prove fatal to the polypeptide encoded by a heterologous nucleic acid mol. fused to the genomic streptavidin nucleic acid mol. In the various embodiments, fusion proteins produced from these vectors are provided. In particular embodiments, fusion proteins comprising a single chain antibody and streptavidin (scFvSA) are provided as are vectors encoding the same. The single chain antibodies are directed to cell surface antigens or cell-assocd. stromal or matrix proteins such as CD20, CD45, CD22, CD52, CD56, CD57, EGP40, NCAM, CEA, TAG-72, mucins (MUC1-7), 13HCG, EGF receptor, IL-2 receptor, her2/neu, Lewis Y, GD2, GM2, tenascin, sialylated tenascin, somatostatin, activated tumor stromal antigen or neoangiogenic antigens. Also provided, are methods of using the fusion proteins of the present invention, in the absence and presence of a radiation-sensitizing agent, and in particular, the use of scFvSA fusion proteins as diagnostic markers or as a cell specific targeting agents.

AB The epithelial cell adhesion mol. (EpCAM) is a transmembrane protein assocd. with a variety of carcinomas, where EpCAM is often strongly up-regulated or, as in the case of squamous cell carcinomas, de novo expressed. The mol. mechanisms underlying the transcriptional regulation of EpCAM are poorly understood. So far, a 570bp fragment has been cloned and shown to have specific transcriptional activity, which was neg.-regulated upon the induction of the transcription factor NF-.vkappa.B. In the present study we have cloned a 1100bp fragment of the EpCAM ***promoter*** contg. the 570bp fragment and addnl. 550bp upstream. We demonstrate that both fragments have strong synergistic effects with respect to transcriptional activity in EpCAM-pos. cells. Furthermore, the 1100bp fragment was likewise neg.-regulated upon TNF.alpha. and IFN.alpha. treatment, thus retaining silencer sequences.

AB Disclosed are methods for diagnosing, monitoring the progression of, and treating a prostate disorder based upon genes that are differentially expressed in prostate disorders. Also disclosed are methods for identifying agents useful in the treatment of a prostate disorder, methods for monitoring the efficacy of a treatment for a prostate disorder, methods for inhibiting the proliferation of a prostate cell, and prostate-specific vectors including the ***promoter*** of these genes. A dendrogram of 55 exptl. samples that are grouped according to overall similarity in level of expression of a subset of 3,530 genes that have varied most across the samples is provided. Expression levels of highly ranked genes in normal and malignant prostate tissues are provided. Furthermore, the top 25 or 50 genes (with ref. GenBank accession nos.) overexpressed in prostate malignant tissues or cell lines are identified as the diagnostic markers and therapeutic targets for prostate related disorders. They include genes for hepsin, prostate differentiation factor, alpha-methylacyl-CoA racemase, fatty acid synthase, and prostate specific antigen (alternative splice form 2 and 3). Specifically, the amplification of two marker genes (hepsin and PLAB) are detected at the mRNA level from selected prostate tissues.

AB The invention provides polynucleotides and polypeptides encoded therefrom having advantageous properties, including an ability of the polypeptides to preferentially bind a CD28 or CTLA-4 receptor at a level greater or less than the ability of human B7-1 to bind CD28 or CTLA-4, or to induce or inhibit altered level of T cell proliferation response greater compared to that generated by human B7-1. The polypeptides and polynucleotides of the invention are useful in therapeutic and prophylactic treatment methods, gene therapy applications, and vaccines. Novel ligands were generated by shuffling of sequences from cDNAs for B7-1 ligands from human, rhesus monkey, baboon, orangutan, cow, cat and rabbit. Ligands were screened for using a FACS assay. CDNA libraries were introduced into animal cells that were then screened for their ability to bind a labeled CD28 or CTLA-4 using FACS. Clones were screened for their preferential binding of CD28 vs. CTLA-4. Candidate clones were then tested for their ability to stimulate T cell proliferation.

AB A 400 bp fragment of the spermatogonia-specific Stra8 locus was sufficient to direct gene expression to the germinal stem cells in transgenic mice. A fractionation procedure was devised, based on immunomagnetic sorting of cells in which the ***promoter*** drives the expression of a surface functionally neutral protein tag. The purified cells expressed the known molecular markers of spermatogonia Rbm, cyclin A2 and ***EP*** - ***Cam*** , and the beta1- and alpha6-integrins characteristic of the stem cell fraction. A 700-fold enrichment in stem cells was determined by the ability of the purified fractions to re-establish spermatogenesis in germ cell-depleted recipient testes.

AB Disclosed herein are vaccines and methods for inducing an immune response against cancer cells and cells infected with intracellular parasites. Vaccines having housekeeping epitopes are disclosed. The housekeeping epitope is formed by housekeeping proteasomes in peripheral cells, but not by professional antigen presenting cells. A vaccine contg. a housekeeping epitope that is derived from an antigen assocd. with a peripheral target cell can thus direct an immune response against the target cell. Methods of treatment are also disclosed, which involve administering a vaccine having a housekeeping epitope.

AB The human pancarcinoma-associated ***epithelial*** ***glycoprotein*** - ***2*** (EGP-2), a Mr 38,000 transmembrane antigen also known as ***17*** - ***1A*** or ***Ep*** - ***CAM*** , is commonly used for targeted immunotherapy of carcinomas because it is strongly expressed by most carcinomas. EGP-2 is, however, also expressed in most normal epithelia. To evaluate anti-EGP-2-directed treatment-associated effects on tumors and on EGP-2-positive normal tissue, we generated EGP-2-expressing transgenic mice. A 55-kb DNA fragment consisting of the 14-kb genomic coding sequence of the human EGP-2 gene with apprx10-kb-upstream and apprx31-kb-downstream sequences was isolated and used to direct EGP-2 expression in an epithelium-specific manner. In the EGP-2 transgenic mice, EGP-2 appeared to be specifically expressed in all of those epithelial tissues that also express EGP-2 in humans, whereas all of the other tissues were negative. The specific in vivo localization of the i.v. administered anti-EGP-2 monoclonal antibody MOC31 was studied in EGP-2-positive and -negative tumors induced s.c. in this EGP-2 transgenic mouse model. Immunohistochemical analysis showed specific localization of MOC31 in the EGP-2-positive tumors but not in the EGP-2-negative tumors. No anti-EGP-2 monoclonal antibody localization was observed in any of the EGP-2-positive normal mouse tissues, which indicated a limited in vivo accessibility. In conclusion, an EGP-2 transgenic mouse model has been generated that expresses the EGP-2 antigen as in humans and, therefore, can serve as a model to evaluate the efficacy and safety of a variety of anti-EGP-2-based immunotherapeutic modalities in both tumors and normal tissue.

AB The present invention provides vectors for expressing genomic streptavidin fusion cassettes which include inducible promoters and various linkers and signal sequences. In the various embodiments, fusion proteins produced from these vectors are provided. In particular embodiments, fusion proteins comprising a single chain antibody (huNR-LU-10) and genomic streptavidin are provided as are vectors encoding the same. Also provided, are methods of using the fusion proteins of the present invention, and in particular, the use of scFvSA fusion proteins involving B9E9 as diagnostic markers or as a cell specific targeting agents. In addn. tetravalent antibodies that contact a fusion protin forming a tetrametric complex which may comprise a tumor cell surface-assocd. protein and a streptavidin portion capable of binding biotin and a biotinylated radionuclide contg. compd. A immunoreactivity assay is described in addn. to monitoring of blood clearance and tumor uptake of fusion proteins. Some adenocarcinomas and hematol. malignancies such as non-Hodgkin's lymphoma may be treated with these fusio-protein expressing vectors. This system offers the expression of a genomic streptavidin gene fusion as a sol. protein into the periplasmic space of Escherichia coli where it undergoes spontaneous folding. This expression offers efficient protein folding where one does not need to purify and refold the protein expressed.

AB The present invention provides recombinant vectors encoding and expressing at least three or more costimulatory mols and host cells infected by the vector. The recombinant vector may addnl. contain a gene encoding one or more target antigens or immunol. epitope as well as cytokine, chemokine, or Flt-3L. A method of making a recombinant poxvirus, of enhancing an immune response of an individual by administering a recombinant vector, and of treating or preventing a disease by activating a T lymphocyte, are also presented. Further describes are a method of making a progenitor dendritic cell or dendritic cell, of assessing the efficacy of a vaccine against a target antigen, and of screening for novel immunogenic peptides. The synergistic effect of these costimulatory mols. on the enhanced activation of T cells was demonstrated. The degree of T-cell activation using recombinant vectors contg. genes encoding three costimulatory mols. was far greater than the sum of recombinant vector constructs contg. one costimulatory mol. and greater than the use of two costimulatory mols. Results employing the triple costimulatory vectors were most dramatic under conditions of either low levels of first signal or low stimulator to T-cell ratios. This phenomenon was obsd. with both isolated CD4+ and CD8+ T cells. The recombinant vectors of the present invention are useful as immunogenes and vaccines against cancer and pathogenic micro-organisms, and in providing host cells, including dendritic cells and splenocytes with enhanced antigen-presenting functions.

AB A method is disclosed for inducing cell-mediated immunity against cellular antigens. More specifically, the invention provides for a method for inducing cytotoxic T-lymphocyte immunity against weak antigens, notably self-proteins. The method entails that antigen presenting cells are induced to present at least one CTL epitope of the weak antigen and at the same time presenting at least one foreign T-helper lymphocyte epitope. In a preferred embodiment, the antigen is a cancer specific antigen, e.g. prostate specific membrane antigen (PSM), Her2, or FGF8b. The method can be exercised by using traditional polypeptide vaccination, but also by using live attenuated vaccines or nucleic acid vaccination. The invention furthermore provides immunogenic analogs of PSM, Her2 and FGF8b, as well as nucleic acid mols. encoding these analogs. Also vectors and transformed cells are disclosed. The invention also provides for a method for identification of immunogenic analogs of weak or non-immunogenic antigens.

AB There is considerable evidence that significant factor underlying the individual variability in response to disease, therapy and prognosis lies in a person's genetic make-up. There have been numerous examples relating that polymorphisms within a given gene can alter the functionality of the protein encoded by that gene thus leading to a variable physiol. response. In order to bring about the integration of genomics into medical practice and enable design and building of a technol. platform which will enable the everyday practice of mol. medicine a way must be invented for the DNA sequence data to be aligned with the identification of genes central to the induction, development, progression and outcome of disease or physiol. states of interest. According to the invention, the no. of genes and their configurations (mutations and polymorphisms) needed to be identified in order to provide crit. clin. information concerning individual prognosis is considerably less than the 100,000 thought to comprise the human genome. The identification of the identity of the core group of genes enables the invention of a design for genetic profiling technologies which comprises of the identification of the core group of genes and their sequence variants required to provide a broad base of clin. prognostic information - "genostics". The "Genostic" profiling of patients and persons will radically enhance the ability of clinicians, healthcare professionals and other parties to plan and manage healthcare provision and the targeting of appropriate healthcare resources to those deemed most in need. The use of this invention could also lead to a host of new applications for such profiling technologies, such as identification of persons with particular work or environment related risk, selection of applicants for employment, training or specific opportunities or for the enhancing of the planning and organization of health services, education services and social services.

AB The present invention relates to the field of glycosylation engineering of proteins. More particularly, the present invention is directed to the glycosylation engineering of proteins to provide proteins with improved therapeutic properties, e.g., antibodies, antibody fragments, or a fusion protein that includes a region equiv. to the Fc region of an Ig, with enhanced Fc-mediated cellular cytotoxicity. The antibodies or fusion proteins with enhanced Fc-mediated cellular cytotoxicity are expressed in host cells engineered to also express a glycoprotein-modifying glycosyl transferase, e.g. .beta.(1,4)-N-acetylglucosaminyltransferase III or V, .beta.(1,4)-N-galactosyltransferase, and mannosidase II.

AB Tomato and potato leucine aminopeptidase (LAP) mRNAs are induced in response to mech. wounding and the wound signal mols., ABA and jasmonic acid. Here, we report the isolation of two LAP genes, LAP17.1A and LAP17.2, from tomato. Functional anal. in transgenic tomato and potato plants show that fusions of the corresponding 5' non-coding regions to the gusA gene are constitutively expressed in flowers and induced in leaves upon wounding or by treatment with Me jasmonate (MeJA). Comparison of the 5' non-coding regions of the two genes revealed a region from -317 to -3 relative to the ATG, which is strongly conserved in both promoters. This 0.3 kb proximal ***promoter*** fragment is sufficient to direct flower-specific and MeJA-inducible GUS activity in transgenic potato plants, and thus contains a MeJA-responsive element that mediates induction by MeJA. Dimeric TGACG motifs or G-box elements similar to those found in other MeJA-inducible genes are not obsd. in this region, which suggests that a different DNA sequence is involved in MeJA induction of the LAP genes.

AB Antibody-dependent cellular cytotoxicity (ADCC) is considered to be the major mechanism through which tumour cells, upon treatment with anti-tumour MAbs, are eliminated in vivo. However, the relative importance of various parameters that influence the efficacy of ADCC is unclear. Here we present in vitro data on the impact of MAb affinity and antigen density on ADCC, as obtained by comparison of two MAbs against the tumour-associated antigen ***Ep*** - ***CAM*** . The low-affinity MAb ***17*** - ***1A*** (Ka = 5 X 107 M-1) currently used for therapy, and the high-affinity MAb 323/A3 (Ka = 2 X 109 m-1), were compared in ADCC experiments against murine and human tumour target cells transfected with the ***Ep*** - ***CAM*** cDNA under the control of an inducible ***promoter*** to enable regulation of the target antigen expression levels. Data obtained from these studies revealed that the high-affinity MAb, in contrast to the low-affinity MAb, could mediate killing of tumour cells with low antigen expression levels. Even at comparable MAb-binding levels, ADCC mediated by the high-affinity MAb was more effective. The kinetics of ADCC was also found to be determined by the level of antigen expression, and by the affinity and the concentration of the MAb used. The efficacy of ADCC with both low- and high-affinity MAbs further depended on adhesive interactions between effector and target cells mediated by CD18. However, at every given MAb concentration these interactions were of less importance for the high-affinity MAb than for the low-affinity MAb. As heterogeneity of a target antigen expression is a common feature of all tumours, and some tumour cells express very low levels of the antigen, the use of high-affinity MAbs in immunotherapy may significantly improve the clinical results obtained to the present date in the treatment of minimal residual disease.

AB Progress in understanding the dynamics of gene expression has been hampered by lack of a strategy for continuously monitoring this process within normal, living cells. Here, the authors employed a modifn. of conventional luciferase technol. to make single and repeated real-time measurements of PRL gene expression from individual, living lactotropes from nursing rats. Cells were individually transfected by microinjection with a PRL ***promoter*** /luciferase reporter construct. Levels of PRL gene transcription were quantified by photonic imaging in the same cells before and after 24 h of culture in the presence or absence of the dopamine agonist bromocryptine or ***EGF*** , ***2*** well known regulators of PRL gene transcription. These cells were found to be remarkably heterogeneous with respect to basal PRL gene expression and that the degree of activity within a single cell could fluctuate greatly over time under basal culture conditions. Treatment with bromocryptine or EGF induced predictable and reversible changes in the av. responses obsd., yet individual cells displayed marked differences in responses to these agents. These findings demonstrate the utility of this paradigm for monitoring dynamics of gene expression within normal, living cells of any type. Moreover, they provide a mol. basis for the secretory heterogeneity and plasticity that have come to be known as hallmarks of lactotrope cell function.

AB A method is described for the cloning and expression of human .beta.2-microglobulin (B2M) cDNA in vector host cells which allows the construction of B2M fusion proteins with antigenic sequences from various etiol. agents or tumors. Preferred antigenic sequences are derived from the third variable domain (V3 loop) of an envelope protein of a lentivirus. These fusion proteins can be used as prophylactic or immunotherapeutic vaccines to induce neutralizing antibody responses. Thus, B2M cDNA was inserted into the pHILD1 expression vector for expression in the Pichia pastoris system. The expression vector includes an AOX ***promoter*** sequence and an .alpha.-factor or Pho1 leader sequence to obtain secretion of the fusion protein from the yeast cells. Within the Pichia pastoris expression system, the B2M gene was fused at its 5' end to the Sendai virus epitope (FAPGNYPAL-GGGGG, where the pentaglycine is a short linker) or to the influenza A virus nucleoprotein epitope (GILGFVFTL-GGGGGGSSS). Prodn. levels from strains with the .alpha.-factor leader sequence were .apprx.150 mg/L. The hybrid Sendai-B2M product was shown to induce Sendai nucleoprotein-specific cytotoxic T-lymphocytes.

AB Methods of introducing nucleic acids into cells of an individual using agents that stimulate nucleic acid uptake or expression or the inflammatory response are described. The method avoids the use of viral or retroviral particles. The transforming nucleic acid encodes an antigenic peptide and so may be useful in therapeutics or prophylaxis. Methods of prophylactically and therapeutically immunizing an individual against HIV without the use of retroviral proteins or particles are disclosed. Expression cassettes for manuf. of antigens of HIV-1 in animal cells were constructed by std. methods. These were used to transform tumor cell lines not normally recognized by a mouse host. Mice injected with these transformed cells mounted a strong cytotoxic response that completely eliminated tumors that would normally kill the animal in 12 wk. Injection of mice with an expression vector carrying an expression cassette for gp160 in combination with bupivacaine to stimulate inflammation and cell proliferation resulted in a strong immune response to gp160. The response was stronger than from mice injected with gp160 or injected with the expression vector without the use of bipuvacaine.

AB Elements controlling high expression of the ***17*** - ***1A*** antigen gene in pancreatic carcinoma cells (Capan 2) reside within the two regions: proximal (-193 to +3) and distal (-877 to -518). We demonstrate here that some factors present in nuclear extracts from nonexpressing cells bind specifically to the control elements, important for gene expression. Our results suggest that nonexpressing cells may either lack at least one of the factors necessary for activation or may contain their modified forms. A major difference between expressing and nonexpressing cells was found in the region containing core enhancer sequence. Moreover, nonexpressing cells display a complex pattern of DNA-protein interactions in this region, suggesting that these cells contain factors acting negatively mainly on the enhancer sequence. Our results however, indicate that the mechanism of repression is much more complicated than expected.

AB The gene encoding the carcinoma-associated antigen defined by the monoclonal antibody GA733 is a member of a family of at least two type I membrane proteins. This study describes the mechanism of evolution of the GA733-1 and ***GA733*** - ***2*** genes. A full-length cDNA clone for GA733-1 was obtained by screening a human placental library with a genomic DNA probe. Comparative analysis of the cDNA sequence with the previously determined genomic sequence confirmed that GA733-1 is an intronless gene. The ***GA733*** - ***2*** gene encoding the monoclonal antibody-defined antigen was molecularly cloned with a cDNA probe and partially sequenced. Comparison of ***GA733*** - ***2*** gene sequences with the previously established cDNA sequence revealed that this gene consists of nine exons. The putative ***promoter*** regions of the GA733-1 and ***GA733*** - ***2*** genes are unrelated. These findings suggest that the GA733-1 gene was formed by the retroposition of the ***GA733*** - ***2*** gene via an mRNA intermediate. Prior to retroposition, the ***GA733*** - ***2*** gene had been affected by exon shuffling. Analysis of ***GA733*** - ***2*** exons revealed that many delineate structural motifs. The GA733-1 retroposon was localized either to chromosome region 1p32-1p31 or to 1p13-1q12, and the ***GA733*** - ***2*** founder gene was localized to chromosome 4q.

AB We have tested transforming growth factor .beta. (TGF.beta.) in the two-stage BALB/c 3T3 cell transformation assay for possible tumor-promoting activity, since it has several effects similar to those of tumor-promoting phorbol ester. After initiation of BALB/c 3T3 cells with 3-methylcholanthrene, treatment with TGF.beta. at 1 ng/ml alone or in combination with epidermal growth factor (EGF) for 4 weeks enhanced the number of transformed foci by 5- to 6-fold in comparison with uninitiated cells. Initiation treatment alone induced no or very few transformed foci in several assays. Treatment with phorbol-12,13-didecanoate (PDD) at 100 ng/ml for 4 weeks enhanced the number of transformed foci in initiated BALB/c 3T3 cells by 4- to 5-fold in comparison with uninitiated cells. Thus, TGF.beta. at 1 ng/ml is as potent as PDD at 100 ng/ml for tumor-promoting activity in the two-stage BALB/c 3T3 cell transformation assay. The enhancing effect of TGF.beta. was dose-related inthe dose range tested (0.03-1 ng/ml) and was not reversible. Some of the foci induced by combined MCA-TGF.beta.-EGF treatment were cloned, and eight out
of nine clones tested produced tumors in nude mice. TGF.beta. (1 ng/ml) plus ***EGF*** ( ***2*** ng/ml) increased the saturation density to a similar extent as PDD (100 ng/ml) but did not affect the growth of BALB/c 3T3 cells. We observed no change in junctional intercellular communication, as measured by the dye transfer method, when cells were treated with TGF.beta. during the two-stage BALB/c 3T3 cell transformation assay. Nevertheless, there was selective communication between transformed and surrounding nontransformed cells; MCA-TGF.beta. transformed cells intercommunicated among themselves but not with surrounding nontransformed cells. Our results indicate that TGF.beta. has potent tumor-promoting activity in vitro, but that this activity is not mediated by a complete blockage of intercellular communication, as is suggested for phorbol ester tumor promoters.

AB The gastrin-releasing peptide (GRP) is expressed in most types of small cell ***lung*** ***carcinoma*** (SCLC) and the GRP ***promoter*** is thought to be potentially useful for tumor-specific expression of the suicide gene in SCLC. We constructed an adenovirus

containing the herpes simplex thymidine kinase suicide gene driven by the GRP ***promoter*** (AdGRP-TK) and transfected it into GRP-expressing SCLC cells (SBC5) to confer sensitivity to ganciclovir (GCV). After infection with AdGRP-TK, SBC5 cells became more sensitive to GCV in vitro. In nude mice, a subcutaneously-inoculated tumor of SBC5 cells infected with AdGRP-TK in advance regressed completely after intraperitoneal administration of GCV. These results suggest that adenovirus-mediated gene transfer of the suicide gene followed by pro-drug treatment may be applicable to SCLC.

AB To investigate the specific transduction of a suicide gene into human small cell ***lung*** ***carcinoma*** (SCLC) cells, we explored the ***promoter*** region of the neuron specific enolase (NSE) gene as a tumor-specific ***promoter*** . In Northern blot anal., NSE mRNA was expressed more abundantly in the SBC3 human SCLC cell line than in the RERF human SCLC cell line, the A549 human lung adenocarcinoma cell line and the HeLa human uterine cervix epitheloid carcinoma cell line. A reporting vector contg. the NSE ***promoter*** (pNSE-LUC) exhibited higher luciferase activity in SBC3 than in the other three cell lines. After transfecting an expression vector contg. the NSE ***promoter*** -bound HSV-TK gene. (pNSE-TK) into the cells, we measured their sensitivity to ganciclovir (GCV). In SBC3, pNSE-TK transfected cells showed about the same sensitivity to GCV as non-transfected (parental) cells. Though the NSE ***promoter*** itself is not optimal for use in suicide gene transfer to SCLC cells, it might be applied as a tumor-specific ***promoter*** after enhancement of its activity.

AB The suppressive effects of a murine genomic p53 minigene contg. an Arg-Leu substitution at its encoding amino acid 172 on biol. behaviors of human carcinoma cell were explored and its potential application in cancer gene therapy was evaluated. This mutant p53 gene which lacked of exon 1 and intron 1 expression vector driven by CMV ***promoter*** was co-transfected with PCMVneo into PG cell in which dominant neg. p53 pre-exists by LipofectaMINE and electroporation methods. A wild-type and another kind of genomic mutate-type p53 gene expression vector were transfected. The latter p53 gene encoding protein contained an Arg-His substitution at the same position, and pBLuscript plasmid was used as control. All transfectants were screened by 500 .mu.g/mL geneticin and identified by mouse specific p53 mRNA RT-PCR and Northern blot anal. The biol. behavior changes were studied by colony formation and TUNEL test together with in-situ clone regression for chemosensitivity of anti-cancer drugs after transfection. The transfecting effects of this unusual p53 gene were surprisingly strong. They were more significant than those of the wild-type p53 and could suppress the formation of transgenic colonies and passage. The transgenic colonies were sensitive to be treated in adriamycin and 5-Fu, and the gene transient expression could give cell apoptosis. Codon 172 mutant (Arg-Leu) p53 genomic DNA exhibited a strong suppressive transfecting effects on carcinoma cell, so it was a possible candidate to be used in cancer gene therapy.

AB We have used transient expression assays to identify a cis-acting region in the 5' flanking sequence of murine c-mos which, when deleted, allows expression from the c-mos ***promoter*** in NIH 3T3 cells. This negative regulatory sequence, located 400 to 500 nucleotides upstream of the c-mos ATG, also inhibited expression from a heterologous ***promoter*** . In addition to NIH 3T3 cells, the c-mos negative regulatory sequence was active in BALB/3T3 cells, PC12 rat pheochromocytoma cells, and A549 human ***lung*** ***carcinoma*** cells. Site- ***specific*** mutagenesis identified three possibly interacting regions that were involved in negative regulatory activity, located around -460, -425, and -405 with respect to the ATG. RNase protection analysis indicated that once the negative regulatory sequences were deleted, transcription in NIH 3T3 cells initiated from the same transcription initiation sites normally utilized in spermatocytes, approximately 280 nucleotides upstream of the ATG. Deletions beyond the spermatocyte ***promoter*** , however, allowed transcription initiation from progressively downstream c-mos sequences. Deletion or mutation of sequences surrounding the oocyte ***promoter*** at -53 also had little effect on expression of c-mos constructs in NIH 3T3 cells. Therefore, the major determinant of c-mos expression in NIH 3T3 cells was removal of the negative regulatory sequence rather than the utilization of a unique ***promoter*** . The c- mos negative regulatory sequences thus appear to play a significant role in tissue-specific c-mos expression by inhibiting transcription in somatic cells.

AB The alpha folate receptor (alphaFR) is a membrane glycoprotein that binds folates, and mediates their uptake and that of antifolate drugs. alphaFR is absent on ovarian surface epithelium (OSE) but is detectable during early transforming events in this epithelium, with increasing expression levels in association with tumor progression. Analysis of transcriptional regulation of the alphaFR gene have revealed two ***promoter*** regions, P1 and P4, flanking exons 1 and 4, respectively, and a requirement for three SP1 sites and an INR element for optimal P4 activity. Here, we focused on the P1 transcription regulation in ovarian carcinoma cells. RNase protection assay indicated that the 5'-untranslated region is heterogeneous because of different start sites and alternative splicing of exon 3. A core region of the P1 ***promoter*** was sufficient for maximal ***promoter*** activity in

ovarian carcinoma cell lines but not in OSE cells or in alphaFR-nonexpressing cell lines. Deletion and mutation analysis of this core ***promoter*** identified a cis- ***regulatory*** ***element*** at position +27 to +33 of the untranslated exon 1, which is responsible for maximum P1 activity. This element formed an abundant DNA-protein complex with nuclear proteins from ovarian cancer cells but not from other cell lines or OSE cells. Competition experiments and supershift assays demonstrated binding of the P1 cis- ***regulatory*** ***element*** by a transcription factor involved in embryonic development, the variant hepatocyte nuclear factor-1 (vHNF1). Analysis of RNA from various cell lines and surgical specimens confirmed that vHNF1 is expressed in ovarian carcinomas. Thus, vHNF1 regulates tissue- ***specific*** transcription in ovarian ***carcinoma*** .

AB Human folate receptor alpha (FRalpha) is a folate-binding protein that is ***selectively*** overexpressed in ovarian ***carcinoma*** and has been regarded as a suitable target antigen for immunotherapy purposes. To study the possible use of this antigen in DNA vaccination, FRalpha cDNA was ligated into the VR1012 (Vical) expression vector under the transcriptional control of the cytomegalovirus ***promoter*** . A total of 100 mug of purified plasmid DNA was injected intramuscularly in BALB/c mice three times at 14-day intervals. At 10 days after the second injection, the sera of the animals (100%) displayed significant antibody titers (by indirect immunofluorescence and fluorescence-activated cell sorter analysis) against syngeneic C26 cells transduced with FRalpha, but not against unmodified C26 cells. Immunoglobulin G2a was the predominant isotype. In addition, specific cytotoxic T lymphocyte activity against FRalpha-transduced C26 cells could be detected in splenocytes from all immunized animals. Coinjection of a plasmid containing interleukin-2 cDNA increased both antibody titers and cytotoxic T lymphocyte activity. Challenge by subcutaneous injection with FRalpha-transduced C26 cells (performed 10 days after the third injection) showed a statistically significant delay in tumor growth. Vaccination with the FRalpha and interleukin-2 cDNA mixture, which was performed after an intravenous injection of FRalpha-transduced cells, enhanced the mean survival time and reduced the number of ***lung*** metastases, thus suggesting that such vaccination is effective even against preexisting tumor cells.

AB Purpose and Experimental Design: Recent evidence shows that the presence of ***promoter*** hypermethylation of tumor suppressor genes has been demonstrated in the serum DNA of patients with various cancers such as ***lung*** , liver, and head and neck cancer. We have examined ***promoter*** hypermethylation of the p16 gene in esophageal squamous cell ***carcinoma*** (SCC) using methylation- ***specific*** PCR to detect tumor DNA in the serum. Results: Aberrant ***promoter*** methylation of the p16 gene was detected in 31 of 38 (82%) esophageal SCCs. Subsequently, we tested for ***promoter*** methylation in the paired serum DNA of 31 patients with a p16 alteration in the primary tumor. We found that 7 of these 31 (23%) patients had the same methylation changes in the serum DNA. Conclusions: This result indicates that ***promoter*** methylation present in the tumors of esophageal SCC patients can be detected in the serum of the same patient and that this approach can potentially be used for the screening and monitoring of the disease.

AB Survivin is expressed in many cancers but not in normal adult tissues and is transcriptionally regulated. To test the feasibility of using the survivin ***promoter*** to induce cancer-specific transgene expression in ***lung*** cancer gene therapy, a vector expressing a luciferase gene driven by the survivin ***promoter*** was constructed and evaluated in vitro and in vivo. It was found that the survivin ***promoter*** was generally more highly activated in cancer cell lines than in normal and immortalized normal cell lines. When delivered i.v. by DNA:liposome complexes, the survivin ***promoter*** was more than 200 times more cancer specific than the cytomegalovirus ***promoter*** in vivo. To identify ***lung*** cancer patients who may benefit from gene therapy with the survivin ***promoter*** , survivin protein expression was measured in surgical specimens of 75 non-small-cell ***lung*** cancers and 10 normal ***lung*** tissues by immunohistochem. staining and found that survivin is expressed in most of the non-small-cell ***lung*** cancers tested (81%, 61 of 75) but none of the normal ***lung*** tissues. The survivin ***promoter*** also induced transgene expression of a mutant Bik in cancer cells, which suppressed the growth of cancer cells in vitro and in vivo. These results indicate that the survivin ***promoter*** is a cancer-specific ***promoter*** for various cancers and that it may be useful in cancer gene therapy.

AB The present invention discloses the specificity of multiple transcriptional regulatory elements can be combined to make adenoviral vector systems that selectively target cancer cells and its uses in gene therapy for cancers. The ***promoter*** for telomerase reverse transcriptase (TERT) can be combined in a remarkably synergistic fashion with another ***promoter*** that has expression restricted to cancer cells or a particular tissue type. The two promoters work synergistically for exquisite targeting of the malignant cells-where it causes cell lysis while leaving neighboring healthy cells intact. This invention also includes methods for constructing and selecting the viral vectors, host cells transduced with the vector construct, and the host cells monitored for any effect of the vector.

AB The authors previously developed recombinant adenoviruses carrying herpes simplex virus thymidine kinase (HSVtk) genes to evaluate the possibility of tissue-specific gene therapy for thyroid carcinoma. The HSVtk gene was driven by a minimal thyroglobulin (TG) ***promoter*** (AdTGtk) and a tandemly repeated minimal TG ***promoter*** (Ad2.times.TGtk) to obtain thyroid-specific cell killing ability. Ad2.times.TGtk showed a beneficial effect for tissue-specific gene therapy for TG-producing thyroid carcinoma, but not for undifferentiated thyroid carcinoma. The authors

placed HSVtk gene under the control of human telomerase reverse transcriptase (hTERT) gene ***promoter*** (AdhTERTtk). Tumor-specific transcriptional activity by hTERT ***promoter*** was confirmed. The transduction of HSVtk genes by infection with AdhTERTtk followed by ganciclovir (GCV) treatment showed powerful cytotoxicity for TG-producing and non-TG-producing thyroid carcinoma cell lines but no or little cytotoxicity for normal cell lines. After adenovirus/GCV treatment for ARO tumor-bearing nude mice, AdhTERTtk inhibited the tumor growth. Ad2.times.TGtk/GCV and AdhTERTtk/GCV treatment showed no or very little cytotoxicity in liver, kidney, spleen, thyroid, ***lung*** , and testis. These data suggest a beneficial effect of AdhTERTtk for gene therapy of undifferentiated thyroid carcinoma without toxicity for normal tissues.

AB Two isoforms of the CCAAT-displacement protein/cut homeobox (CDP/Cux) transcription factor have been characterized thus far. The full length protein, p200, which contains four DNA binding domains, transiently binds to DNA and carries the CCAAT-displacement activity. The p110 isoform is generated by proteolytic processing at the G1-S transition and is capable of stable interaction with DNA. Here the authors demonstrate the existence of a shorter CDP/Cux isoform, p75, which contains only two DNA binding domains, Cut repeat 3 and the Cut homeodomain, and binds more stably to DNA. CDP/Cux p75 was able to repress a reporter carrying the ***promoter*** for the cyclin-dependent kinase inhibitor p21 gene and to activate a DNA polymerase .alpha. gene reporter. Expression of CDP/Cux p75 involved a novel mechanism: transcription initiation within intron 20. The intron 20-initiated mRNA (I20-mRNA) was expressed at higher level in the thymus and in CD4+/CD8+ and CD4+ T cells. I20-mRNA was expressed only
weakly or not at all in normal human mammary epithelial cells and normal breast tissues but was detected in many breast tumor cells lines and breast tumors. In invasive tumors a significant assocn. was established between higher I20-mRNA expression and a diffuse infiltrative growth pattern. In agreement with these findings, T47D breast cancer cells stably expressing p75 could not form tubule structures in collagen but rather developed as solid undifferentiated aggregates of cells. Taken together, these results suggest that aberrant expression of the CDP/Cux p75 isoform in mammary epithelial cells may be assocd. with the process of tumorigenesis in breast cancer.

AB The human homolog of the Drosophila Roundabout gene DUTT1 (Deleted in U
Twenty Twenty) or ROBO1 (Locus Link ID 6091), a member of the NCAM family of receptors, was recently cloned from the ***lung*** cancer tumor suppressor gene region 2 (LCTSGR2 or U2020 region) at 3p12. DUTT1 maps within a region of overlapping homozygous deletions characterized in both small cell ***lung*** cancer lines (SCLC) and in a breast cancer line. In this report the authors (a) defined the genomic organization of the DUTT1 gene, (b) performed mutation and expression anal. of DUTT1 in ***lung*** , breast and kidney cancers, (c) identified tumor specific ***promoter*** region methylation of DUTT1 in human cancers. The gene was found to contain 29 exons and spans at least 240 kb of genomic sequence. The 5' region contains a CpG island, and the poly(A)+ tail has an atypical 5'-GATAAA-3' signal. The authors analyzed DUTT1 for mutations in ***lung*** , breast and kidney cancers; no inactivating mutations were detected by PCR-SSCP. However, seven germline missense changes were
found and characterized. DUTT1 expression was not detectable in one out of 18 breast tumor lines analyzed by RT-PCR. Bisulfite sequencing of the ***promoter*** region of DUTT1 gene in the HTB-19 breast tumor cell line (not expressing DUTT1) showed complete hypermethylation of CpG sites within the ***promoter*** region of the DUTT1 gene (-244 to +27 relative to the translation start site). The expression of DUTT1 gene was reactivated in HTB-19 after treatment with the demethylating agent 5-aza-2'-deoxycytidine. The same region was also hypermethylated in six out of 32 (19%) primary invasive breast carcinomas and eight out of 44 (18%) primary clear cell renal cell carcinomas (CC-RCC) and in one out of 26 (4%) primary NSCLC tumors. Furthermore 80% of breast and 75% of CC-RCC
tumors showing DUTT1 methylation had allelic losses for 3p12 markers hence obeying Knudson's two hit hypothesis. The authors' findings suggest that DUTT1 warrants further anal. as a candidate for the tumor suppressor gene (TSG) at 3p12, a region defined by hemi and homozygous deletions and functional anal.

AB The p16INK4a protein inhibits cyclin-dependent kinase 4, a key regulator of progression through the G1 phase of the cell cycle. Methylation of CpG islands in the ***promoter*** region is an important avenue for inactivation of p16. The mechanism of methylation of the p16 ***promoter*** region, however, has not been elucidated. Recent reports investigating p16 methylation in non-small cell ***lung*** cancer (NSCLC) suggest that carcinogens in tobacco smoke induce the DNA methylation process. We investigated the assocn. between methylation of the p16 ***promoter*** region and exposure to tobacco smoke in 185 primary NSCLCs. We also studied the relationship of p16 methylation with mutation of the K-ras and p53 genes, as well as with methylation at the DAP-kinase and p14ARF loci. Finally, we evaluated the prognostic significance of p16 methylation in NSCLC. The prevalence of p16 methylation was greater in squamous cell carcinoma (41%) compared with adenocarcinoma (22%; P = 0.03; Fisher's exact test). Methylation of p16 was significantly assocd. with pack-years smoked (P = 0.007; Wilcoxon rank sum test), duration of smoking (P = 0.0009; Wilcoxon rank sum test), and neg. with the time since quitting smoking (P = 0.03; Wilcoxon rank sum test). No methylation of the nearby p14ARF locus was detected, and methylation of the DAP-kinase locus was not assocd. with either p16 methylation or with exposure to tobacco smoke. In patients with stage 1 adenocarcinoma, p16 methylation was an independent risk factor predicting significantly shorter postsurgery survival (P = 0.03), controlling for the significant effects of other factors, including K-ras mutation. These findings suggest that methylation of CpG islands in tobacco-assocd. cancers occurs in a gene- and tissue-specific manner and is induced directly or indirectly by exposure to tobacco smoke in NSCLC.

AB The invention provides a replication selective adenovirus (Ad) mutant with improved selectively for tumor cells expressing the tumor assocd. antigen in cancers and malignancies, as well as in proliferative cells, characterizing diseases, such as restenosis,intimal proliferative disease and pulmonary hypertension. The selected Ad vectors are driven by promoters of the tumor assocd. antigens, or RNA transcripts or genes therefor, substituting for the activity of at least adenovirus E1A ***promoter*** , which has been deactivated or diminished. Also provided is the use of the Ad vector to deliver therapeutic compns. to patients, as well as a method for treating cancers, such as CEA pos. cancers, or proliferative cell diseases in a patient by administering to the patient an effective amt. of the Ad vector, which may also express a therapeutic gene or peptide, and treatment may also be combined with radiation, chemotherapy or immunomodulatory agents. The Ad is designed to replicate within the tumor cell, thereby spreading throughout the tumor nodule. This permits the delivery of a much higher dose of the heterologous therapeutic protein than previously possible, and the virus achieves a direct, oncolytic effect on the tumor.

TI Tumour-specific arginine vasopressin ***promoter*** activation in small-cell ***lung*** cancer
AU Coulson, J. M.; Stanley, J.; Woll, P. J.

AB Small-cell ***lung*** cancer (SCLC) can produce numerous mitogenic neuropeptides, which are not found in normal respiratory epithelium. Arginine vasopressin is detected in up to two-thirds of SCLC tumors whereas normal physiol. expression is essentially restricted to the hypothalamus. This presents the opportunity to identify elements of the gene ***promoter*** which could be exploited for SCLC-specific targeting. A series of human vasopressin 5' ***promoter*** fragments (1048 bp, 468 bp and 199 bp) were isolated and cloned upstream of a reporter gene. These were transfected into a panel of ten cell lines, including SCLC with high or low endogenous vasopressin transcription, non-SCLC and bronchial epithelium. All these fragments directed reporter gene expression in the five SCLC cell lines, but had negligible activity in the control lines. The level of reporter gene expression reflected the level of endogenous vasopressin prodn., with up to 4.9-fold (s.d. 0.34) higher activity than an SV40 ***promoter*** . The elements required for this strong, restricted, SCLC-specific ***promoter*** activity are contained within the 199-bp fragment. Further anal. of this region indicated involvement of E-box transcription factor binding sites, although tumor-specificity was retained by a 65-bp minimal ***promoter*** fragment. These data show that a short region of the vasopressin ***promoter*** will drive strong expression in SCLC in vitro and raise the possibility of targeting gene therapy to these tumors.

AB The invention relates to the specific expression of heterologous sequences, particularly genes encoding cytotoxic products, in tumor cells under the control of regulatory transcriptional sequences. Particularly preferred promoters include H19 regulatory sequences, the IGF-1 ***promoter*** , and the IGF-2 P3 and P4 promoters from genomically imprinted genes. The invention provides expression constructs and methods of administering such expression constructs. The H19 regulatory sequences facilitate expression of a heterologous gene in five different bladder cancer cell lines (HT-1376, EJ28, T24P, 1197, and UM-UC-3). When transfected into bladder cancer cell, an H19/HSV-TK expression plasmid induces bladder cancer cell-specific cytotoxicity in the presence of ganciclovir. The compns. and methods of the invention are useful in the treatment of cancer.

AB The present invention relates to the use of P-selectin as a targeting agent in radiotherapies for vascular related disease. P-selectin is translocated to the lumen of vascular endothelia as a result of radiation. Thus, P-selecting provides a target for receptor-mediated delivery of drugs, including anticancer drugs and drugs for the treatment of vascular disease. However, P-selectin also plays a role in the activation of certain inflammatory cells and, as such, plays a role in radiation-induced inflammation. By interfering with P-selectin induction of inflammation, it is possible to modulate inflammatory responses to radiation therapy.

AB The gastrin-releasing peptide (GRP) is expressed in most types of small cell lung carcinoma (SCLC) and the GRP ***promoter*** is thought to be potentially useful for tumor-specific expression of the suicide gene in SCLC. We constructed an adenovirus containing the herpes simplex thymidine kinase suicide gene driven by the GRP ***promoter*** (AdGRP-TK) and transfected it into GRP-expressing SCLC cells (SBC5) to confer sensitivity to ganciclovir (GCV). After infection with AdGRP-TK, SBC5 cells became more sensitive to GCV in vitro. In nude mice, a subcutaneously-inoculated tumor of SBC5 cells infected with AdGRP-TK in advance regressed completely after intraperitoneal administration of GCV. These results suggest that adenovirus-mediated gene transfer of the suicide gene followed by pro-drug treatment may be applicable to SCLC.

AB We have used transient expression assays to identify a cis-acting region in the 5' flanking sequence of murine c-mos which, when deleted, allows expression from the c-mos ***promoter*** in NIH 3T3 cells. This negative regulatory sequence, located 400 to 500 nucleotides upstream of the c-mos ATG, also inhibited expression from a heterologous ***promoter*** . In addition to NIH 3T3 cells, the c-mos negative regulatory sequence was active in BALB/3T3 cells, PC12 rat pheochromocytoma cells, and A549 human ***lung*** ***carcinoma*** cells. Site- ***specific*** mutagenesis identified three possibly interacting regions that were involved in negative regulatory activity, located around -460, -425, and -405 with respect to the ATG. RNase protection analysis indicated that once the negative regulatory sequences were deleted, transcription in NIH 3T3 cells initiated from the same transcription initiation sites normally utilized in spermatocytes, approximately 280 nucleotides upstream of the ATG. Deletions beyond the spermatocyte ***promoter*** , however, allowed transcription initiation from progressively downstream c-mos sequences. Deletion or mutation of sequences surrounding the oocyte ***promoter*** at -53 also had little effect on expression of c-mos constructs in NIH 3T3 cells. Therefore, the major determinant of c-mos expression in NIH 3T3 cells was removal of the negative regulatory sequence rather than the utilization of a unique ***promoter*** . The c- mos negative regulatory sequences thus appear to play a significant role in tissue-specific c-mos expression by inhibiting transcription in somatic cells.
